

Hortilife-MGC

The HMGC is a climate computer to control the climate of a department in a horticulture greenhouse. You can choose between controlling the aeration (wind or protected side), the screen (shadow and energy screen), heating (2 heaters or 3 mixture valves), recirculation ventilation, humidification and lighting.

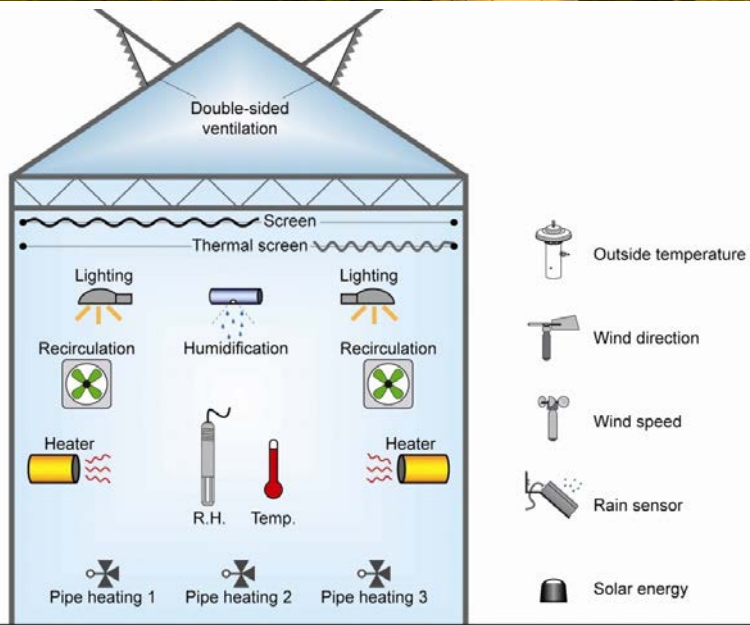

The HMGC was recently expanded to include recirculation ventilation, humidification and lighting. The computer also has switching clocks. The HMGC controls on the basis of the selected sensors and settings.

If a number of departments have to be controlled, the additional computers can be included in a communication network so that data can be forwarded from the weather station. If SmartLink is used, that is the interface between the communication network and a PC, the PC program can be used to operate remotely and read out and log the data from all HMGC computers in the network.
